I. Introduction

As part of the development of a Long-Term Plan (LTP) for Vector Control and Wetlands Management, Suffolk County has determined that local demonstration projects of various kinds are in order. It is widely believed that the most effective, economical, and potentially environmentally benign means of control for salt marsh mosquitoes is to manage their habitat so as to minimize breeding of larvae and so minimize the development of adult populations. Open Marsh Water Management (OMWM) is a guild of techniques that has been developed with the intention of controlling mosquito production but avoiding environmental impacts associated with traditional grid or parallel ditch maintenance. OMWM is intended to enhance habitat for the fish that consume mosquito larvae and to increase access for these fish to potential breeding sites. OMWM is intended to at least partially restore water levels to pre-ditching variability. OMWM is therefore often classified as a means of salt marsh restoration.

There have been several projects that have used OMWM principles or OMWM-like techniques in certain wetlands on Long Island. However, none of these projects have constituted a comprehensive demonstration project of standard OMWM, especially with the overt intention of demonstrating mosquito control feasibility.

Therefore, as part of the development of its LTP for vector control, Suffolk County would like to institute a wide-ranging, long-term, comprehensive demonstration project of several alternatives of OMWM. The US Fish and Wildlife Service (USFWS) has offered to allow portions of the Wertheim National Wildlife Refuge (WNWR), Shirley, to be used for this purpose (see Figure 1).

In order to detect impacts from the OMWM construction projects, pre-project environmental monitoring has been undertaken to establish a data baseline. This report provides a complete set of pre-project data collected for the time period August 2003 to November 2004. Data tables are located at the end of each corresponding section.

WNWR is comprised of approximately 2,550 acres located on the south shore of Long Island at the mouth of the Carmans River. The project locations (four distinct areas, called Area 1, Area 2, Area

3, Area 4 [see Figure 2]) are along the east bank of the Carmans River in the salt marshes found near its confluence with the bay. Generally, the marshes are ditched, and are comprised of nearly monotonous stands of *Spartina alterniflora* (low marsh) and *S. patens* (high marsh). Invasive *Phragmites australis* stands are found throughout the proposed project region. More *Phragmites* are found in Areas 1 and 4 (see Figures 3 and 6) along some of the mosquito control ditches, but *Phragmites* stands are also common in higher elevations of the marshes where they appear to be promoted by fresh water inflows.

Most of the mosquito control ditches were plugged at various times in the 1980s and 1990s. Many of the plugs have failed, either due to physical processes (erosion caused by tides or storms) or undermining by muskrats. However, some are still effectively retaining water within the marsh during tidal cycling. A three year monitoring project conducted between Areas 3 and 4 has been completed by MJ James-Pirri (part of a North-East US project covering 11 different sites, sponsored by USFWS and US Geological Survey [USGS]).

The marsh is an active breeding area for salt marsh mosquitoes, although some other species breed in the refuge as well. Suffolk County Vector Control (SCVC) and USFWS conduct weekly larval monitoring at selected locations. Increases in larval counts result in aerial applications of larvicides (commonly, methoprene). WNWR has also been included in one aerial adulticide application since 1999, intended to prevent West Nile virus infestations in the Bellport-Brookhaven-Mastic-Shirley area.

Sampling has been conducted by a consortium of organizations. These include Cashin Associates (CA), the consultant to the County on the LTP, Ducks Unlimited (DU) (a sub consultant to CA), SCVC, Suffolk County Department of Health Services (SCDHS) including the Public and Environmental Health Laboratory (PEHL), and USFWS staff from WNWR. Researchers from the Goodbred and Cerrato laboratories, Marine Sciences Research Center (MSRC), University at Stony Brook, have also assisted.

It should be noted that the OMWM installations designs were not judged solely on the data collected as part of this project. The OMWM design chosen for Wertheim was incorporated from information

generated by the James-Pirri project as well as prior OMWM/OMWM-like efforts conducted on the south shore in Suffolk County such as Seatuck, Sayville, William Floyd, and Fireplace Neck (Brookhaven hamlet), and similar projects elsewhere on Long Island.

1.1. Station Selection

Transects were identified across each Area, using the USFWS/USGS protocols (James-Pirri et al., 2002). Twenty-four stations were established in each of Areas 1 and 2, and 20 stations were established in Areas 3 and 4, for a total of 88 marsh surface stations. In addition, 10 ditch sampling points (“fish stations”) were established, again using the USFWS/USGS protocols. SCDHS also established four permanent Carmans River water quality monitoring stations (one associated with each Area), and two water quality monitoring stations in navigable sections of the major creeks. Station locations are represented in Figures 3 through 6.

STATION LOCATIONS

1-5-80	2-5-80		

II. Biological Parameters

2.1 Mosquito Breeding Concentration Areas

Mosquito breeding concentration areas were identified throughout the four areas of the marsh in September 2003. For a period of four weeks, the areas were visually inspected five times for small pools of stagnant water that might contain mosquito larvae using the USFWS/USGS protocols (James-Pirri et al., 2002). The pools were selected arbitrarily with a mosquito dipper. Each location containing mosquito larvae was flagged and the GPS coordinates were documented. An assessment of the data was made and the locations of concentrated areas of mosquito larvae were estimated.

2.2 Mosquito Dip Transects

Mosquito larvae were collected during a period of six weeks in September and October 2003, and July and August 2004. Larvae was sampled every 15-20 meters along each transect in all four marsh areas using a mosquito dipper in accordance with USFWS/USGS protocols (James-Pirri et al., 2002). At each sampling location, the nearest standing water within a three meter radius was noted. If standing water was present within a three meter radius, the edges of the standing water were sampled with the mosquito dipper. If a full dipper of water was not possible, the volume increments inside the mosquito dipper were used to estimate the water volume collected. The larvae collected in the mosquito dipper were counted and recorded. If there were more than 100 larvae estimated to be in the dipper, the sample was coded into one of four categories (100 to 200 larvae; 200 to 300 larvae; 300 to 500 larvae; or >500 larvae). The mosquito larvae data is listed in Table 2-1.

Larvae sampling in Area 3

2.3 Vegetation Quadrats

In order to detect differences in the vegetative community composition and abundance, vegetation quadrats were placed at 88 stations in all four areas of the marsh, following USFWS/USGS protocols (James-Pirri et al., 2002). The vegetation was sampled once towards the end of the growing season in October 2003 and September 2004, when plants were easily identifiable. The quadrats measured 1 m² and consisted of a meter stick and dowels (≤ 3 mm in diameter). The dowels were placed perpendicular to the meter stick at 0, 25, 50, 75 and 100 cm. Each dowel was one meter in length with a total of ten marks, each spaced 11.1 cm apart. Thus, the 1 m² quadrant is divided into a grid of 50 evenly spaced points. A thin rod, approximately 3 mm in diameter, was placed vertically to the first sampling point and lowered through the vegetation canopy to the sampling point on the ground. All vegetation species that came in contact with the rod were recorded. Categories other than plant species, such as “water,” “bare ground,” and “wrack and litter” were also recorded. This process was repeated for all remaining points on the sampling quadrat until all 50 points had been sampled. The total number of times each species was recorded was tallied for each quadrat. All vegetation quadrats were sampled within one to two weeks and during a period when the marsh surface was not flooded. The results of the vegetation quadrats are listed in Table 2-2.

2.4 Marsh Composition

In March 2004, marsh composition maps were created using aerial photographs. Areas of high marsh (areas predominantly consisting of *Spartina patens*), low marsh (areas dominated by *S. alterniflora*), and *Phragmites australis* were plotted for all four areas. Marsh composition maps for all four areas are located in Figures 8a through 8d.

2.5 Nekton Sampling

Nekton sampling was conducted in accordance with USFWS/USGS protocols (James-Pirri et al., 2002) at all fish stations located throughout the four marsh areas in October 2003, and June, July and September 2004. A total of 40 samples were collected during each sampling

event using ditch nets. At each sampling point a ditch net, consisting of nylon netting (1.8 inch mesh), was placed along the sides and bottom of a one linear meter section of the ditch. The nets were placed in the ditches at the station locations at least 30 minutes before sampling to minimize any disturbance to the fish caused by placing the net in the ditch. Two doors located on the open ends of the net were pulled to close the net after 30 minutes. Once closed, the ditch net enclosed an area of water one meter long and as wide as the ditch. The net was quickly removed from the water onto the marsh surface where the fish were identified, counted and measured. Water quality parameters were also conducted and recorded at each sampling location. The data collected for all three nekton sampling rounds is listed in Table 2-3.

2.6 Invertebrates

Invertebrates commonly used as a measure of overall habitat function and health. Invertebrate samples were collected from three different areas: marsh surface; mosquito ditches (water column samples); and mosquito ditch sediments (benthic samples). Invertebrate samples were collected from the marsh surface, water column and benthos in fall 2003, and again in August 2004.

Twenty-six marsh surface samples were collected at the randomly selected stations sampled the previous season. The stations were stratified by area, and then again by vegetation type: low marsh (LM), high marsh (HM), and *Phragmites*. One *Phragmites* samples and two samples from both the high marsh and low marsh were taken from Areas 2 and 3. Two *Phragmites* samples and three samples each from high and low marsh were taken in Areas 1 and 4.

A circular metal frame, 30 centimeters in diameter, was used to define the marsh surface sampling area. The frame was inserted into the surface of the marsh to a depth of approximately five centimeters. To ensure capture of mobile insects, a plastic bag was attached to the top of the frame. Soil and root mass within the frame were excavated using a machete and the surface mass was collected in the attached plastic bag. Each marsh surface sample was initially processed in a sorting tray. Plant detritus material was examined to

ensure that sessile species were included in the sample. Samples were then rinsed and sieved through a 0.5 millimeter screen to further separate invertebrates. All specimens caught were preserved in 91% alcohol for later identification. Results of the marsh surface invertebrate sampling are listed in Table 2-4.

Water column invertebrates were sampled at 28 fish stations (seven randomly selected stations in each area). Samples were collected using a D-frame sweep net (500 micron mesh) in accordance with the USFWS/USGS protocols (James-Pirri et al., 2002). Twelve net-sweeps were performed along a one-meter length segment above the benthos at each sampling station. The contents of the net were emptied into individually labeled buckets and processed in separate sorting trays. Dense samples were split in half or thirds during processing. Each sorting tray was examined under light and dense matter was searched and separated from the tray. The trays were examined until no organisms had been observed for 15 minutes. Invertebrates captured were stored in 91% alcohol. Results of the water column invertebrate sampling are listed in Table 2-5.

Benthic samples were collected from the same 28 fish stations as the water column samples. A screened dipper, 10 centimeters in diameter (0.5 mm mesh), was used to collect samples at the top five centimeters of benthos. Three replicate samples were taken from every station and stored in individual plastic bags. Concentrated sugar water (one five-pound bag of sugar per gallon of water) was poured into each sorting tray containing the sample, for better observation (Lewis 2000). Organic material in the tray floated to the surface of the sugar water. All invertebrates observed were removed and preserved in 91% alcohol for later identification. Results of the benthic invertebrate sampling are listed in Table 2-6.

2.7 Invertebrate Analysis

Specimens collected from each invertebrate sample (marsh surface, water column, and benthos) were identified by a taxonomist with the use of a dissecting microscope and magnifying glass. Each invertebrate was identified to the family level using various reference guides (Weiss 1995; Borrer and White, 1970; Emerton, 1961). Assistance was also received from the Cerrato Laboratory, MSRC.

2.8 Vegetation Biomass

As an extension of the vegetation speciation effort described above, vegetation biomass sampling was also conducted. In October 2003 and 2004, half of the transect locations in each area were sampled for above-ground vegetation mass, and a quarter were sampled for above-ground and root mass. The samples stations were selected randomly (stratified by area).

A metal ring, 27 centimeters in diameter, was placed at each above-ground biomass station to determine the vegetation plot to be sampled. The vegetation within the plot was clipped at ground level and bagged separate from dead vegetation. The samples were weighed and dried in an oven at 105 degrees Celsius. After a period of 12 hours, the samples were removed and re-weighed. The sample weight after drying was subtracted from the initial weight to obtain the biomass of the vegetation. Results of the vegetation biomass sampling are listed in Table 2-7.

Measuring and clipping vegetation in high marsh

Soil biomass samples were collected using a seven centimeter core sampler. Prior to obtaining a soil core, the live vegetation above the plot to be sampled was clipped at ground level and stored in individual bags. These samples were analyzed as above. The core sampler was driven into the marsh surface to a depth of 20 centimeters below ground surface (method adopted from Allison 1996). The soil was extracted from the core and placed in individual labeled bags. The soil core samples were weighed and dried in an oven at 105

degrees Celsius. After 24 hours, the samples were removed and re-weighed to obtain the biomass of the soil core. Results of the soil core biomass samples are listed in Table 2-8.

2.9 Bird Surveys

The bird fauna within the refuge have been continuously observed and documented. The marsh lies along migration corridors used by shorebirds, raptors and songbirds. In addition, the refuge supports nine federal and/or New York State designated endangered/threatened avian species. Through anecdotal observations, approximately 22 species of birds have been observed in the marsh. The most abundant species observed include black duck, Northern harrier, and a variety of wading birds. Tree and barn swallows are very common during migrating season. During September and October 2003, swallows were observed in swarms of hundreds. An immature bald eagle has wintered at the Refuge the past several years.

In June 2004, a salt marsh bird survey was performed to provide a baseline estimate for salt marsh breeding bird distribution and abundance (Shriver, 2000). A walking route was established within each of the four study areas by using aerial photos and a GIS coverage. Along this route, 50-meter radius points were located, with point centers being at least 150 meters apart (Figures 9a through 9d). Point counts were conducted from sunrise to 11am, and lasted for 10 minutes. Points were repeated three times during the breeding season (May 20 – July 5), but were not conducted during high winds or heavy rain. All birds seen and/or heard during the 10-minute count were counted. It was noted when the bird was detected during the point count (0-3 minutes, 3-5 minutes, 5-10 minutes), and whether the individual was within three distance categories (0-50m, 50-100m, >100m). Individuals observed along the walking route during travel between points were also noted, as were birds that were flying over the marsh during the survey. Flyovers were not included in any of the summary tabulations. Surveys will be repeated during the 2005 winter season (January 10 – March 10). Data were summarized to reflect the density, diversity, and dominant species detected during the surveys. For each area, birds were also separated into guilds to provide an additional density comparison.

Eighteen species were observed on all four areas combined during the breeding season surveys (see Table 2-9). In Area 1, 14 species were observed, with Marsh Wren and Red-winged Blackbird as the most common species, respectively. When separated into bird guilds, passerines were by far the most common group. Nine species were observed in Area 2, with Marsh Wren and Seaside Sparrow as the most common species, respectively. When separated into bird guilds, passerines were the most common group observed on the marsh. In Area 3, 11 species were observed, with Red-winged Blackbird and Marsh Wren as the most common species, respectively. When separated into bird guilds, passerines were the most common group. Thirteen species were observed in Area 4, with Marsh Wren and Red-winged Blackbird as the most common species, respectively. When separated into bird guilds, passerines were again the most common group observed on the marsh.

The breeding season data reflect a baseline monitoring effort for avian use of the study area marshes at WNWR. Across all study areas, passerines were the most dominant species group, due largely to the high occurrence of Marsh Wren, Red-winged Blackbird, and Seaside Sparrow. All other guilds showed very low densities across all areas. These data will be combined with the upcoming winter season surveys to provide a seasonal perspective of bird use of the marsh.

2.10 Photo Stations

Permanent photo stations were established in an effort to evaluate vegetation community response to marsh alterations in Area 1 and proposed marsh alterations for Area 2. These photo stations will aid in determining if a “stable post-project vegetation regime” is achieved over time. Permanent photo stations were also established in control Areas 3 and 4 to determine if any vegetation changes are occurring naturally over time. The placement of the photo stations in Areas 1 and 2 were determined based on locations of the proposed alterations and the use of aerial photographs. Where possible, photo stations were placed at existing fish stations or transect points. In determining the placement of the photo stations, obstacles that may hinder a clear view of the marsh, such as tall stands of *Phragmites australis*, were taken into consideration; the locations were thus modified to provide a

panoramic view of the immediate area. Initial photo documentation took place in September 2004 to document the existing vegetation conditions. Photo documentation of Area 1 immediately following marsh alterations was recorded in April 2005. Subsequent photo documentation of all Areas took place in September 2005. The locations of the photo stations are depicted in Figures 10a through 10d. A photo comparison for all photo stations are listed in Tables 2-10a through 2-10d.

Bird Species Acronym Key

AMGO	American Golden fin
AMRO	American Robin
BASW	Barn Swallow
BCNH	Black Night Heron
CHSP	Chipping Sparrow
COGR	Common Grackle
COYE	Common Yellowthroat
FICR	Fish crow
GREG	Great Egret
GRHE	Green Heron
HEGU	Herring Gull
MALL	Mallard
MAWR	Marsh wren
MODO	Morning dove
OSPR	Osprey
RBGU	Ring billed Gull
RWBL	Red winged black bird
SESP	Seaside sparrow
SOSP	Song sparrow
SPAR	Sparrow
SSTS	Saltmarsh sharp tailed sparrow
STAR	Starling
TRSW	Tree swallow
WILL	Willet
YEWA	Yellow warbler
